

## SUPPLEMENTARY FIGURES

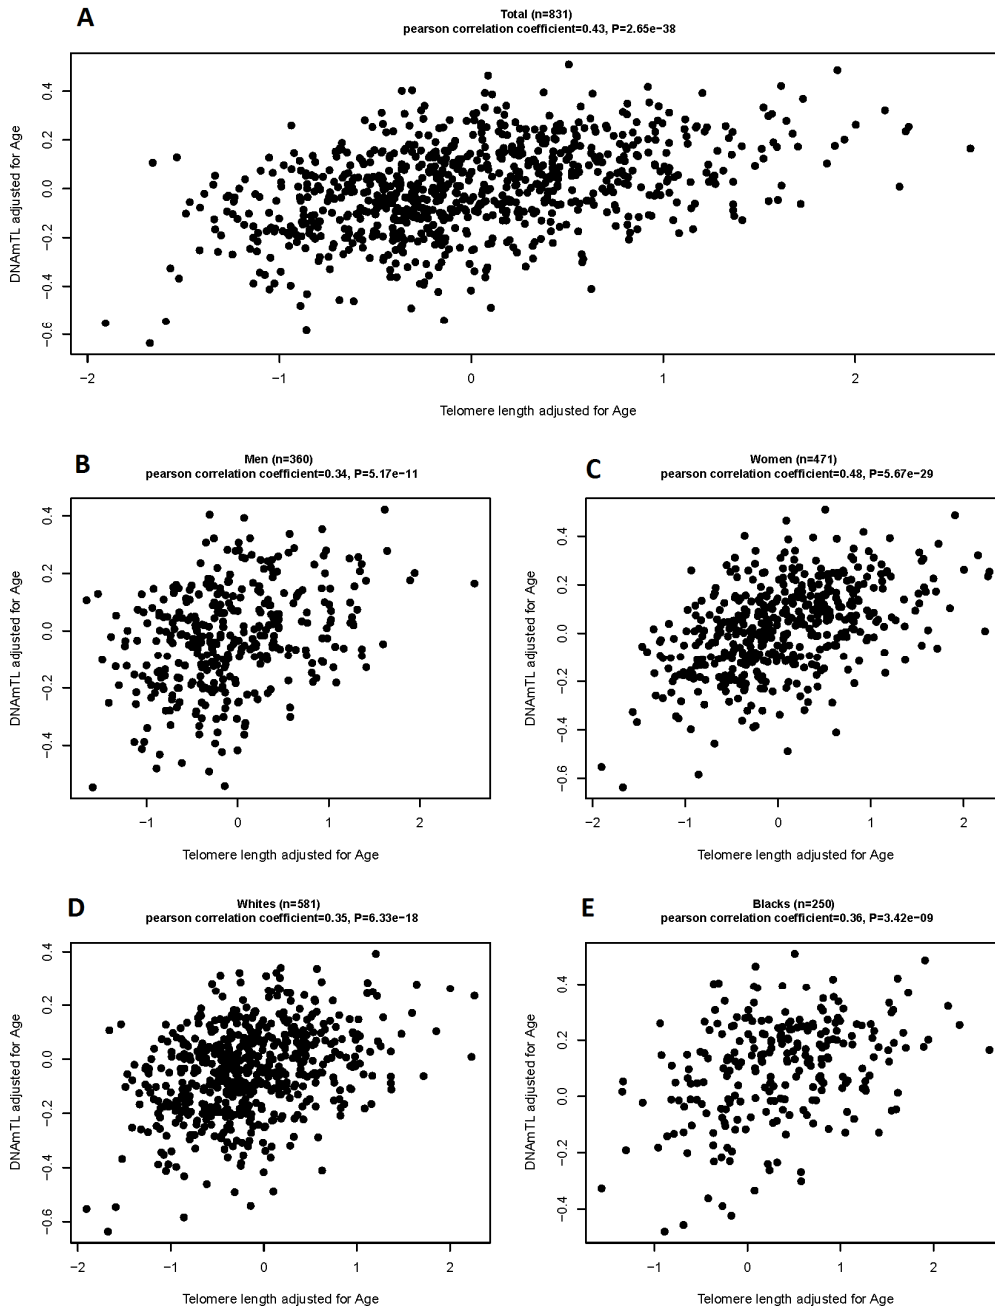

### Supplementary Figure 1. Correlation analysis of age-adjusted DNAmTL versus age-adjusted LTL in FHS.

We present the scatter plots of DNA methylation based age-adjusted leukocyte telomere length (DNAmTLadjAge, in units of kilobase, y-axis) versus age-adjusted Southern blotting based leukocyte telomere length (LTLadjAge) (x-axis, in units of year), using Framingham Heart Study (FHS) Offspring cohort. The analysis was applied to all individuals (panel A) and stratified by gender (panels B&C), respectively.

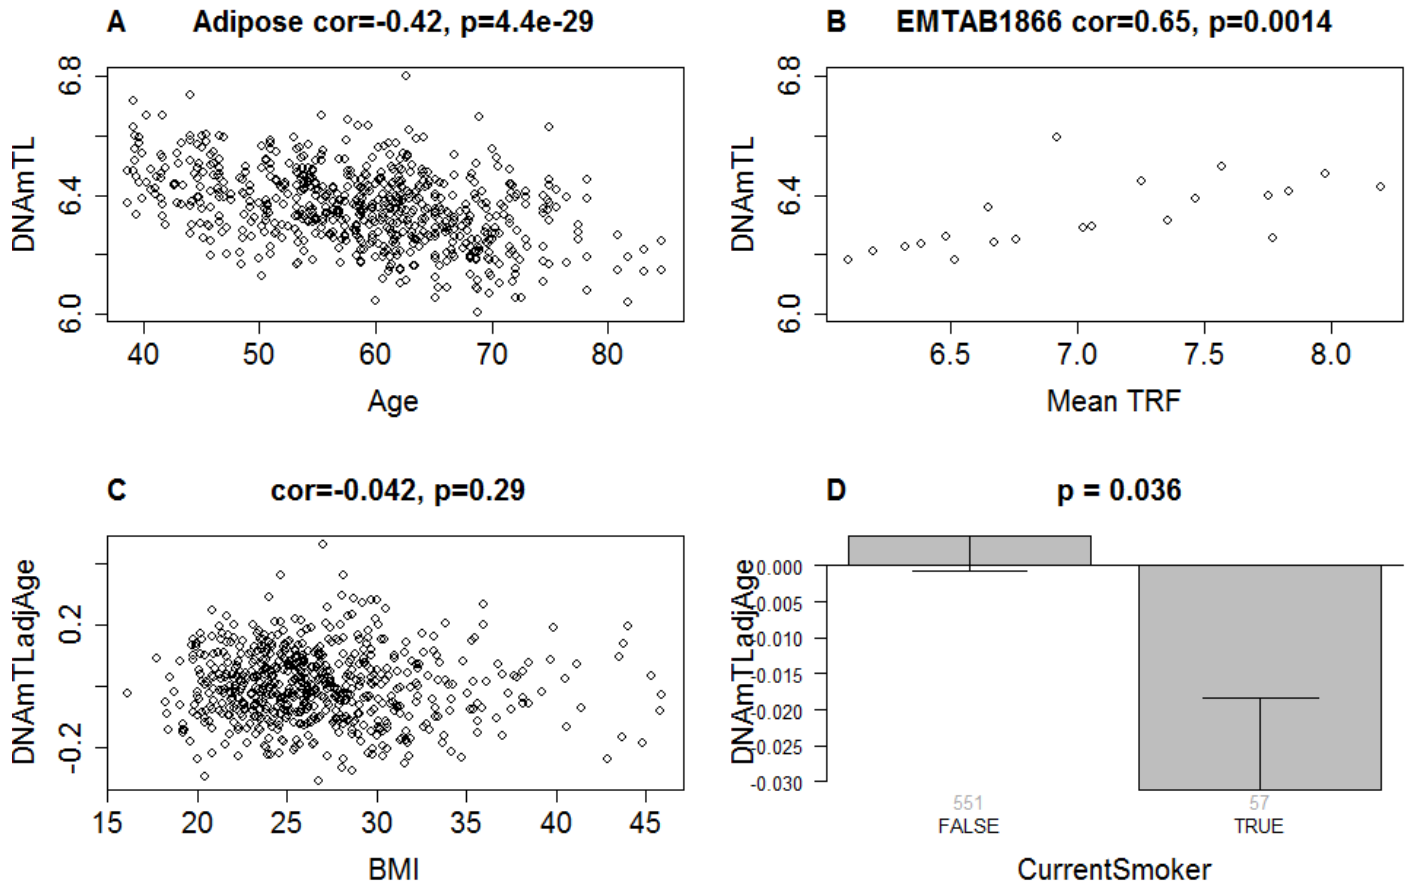

## Supplementary Figure 2. Correlation analysis of age-adjusted DNAmTL versus age-adjusted LTL in BHS cohort.

We present the scatter plots of DNA methylation based leukocyte telomere length (DNAmTL, in units of kilobase, y-axis) versus Southern blotting based leukocyte telomere length (LTL) (x-axis, in units of year), using Bogalusa Herat Study (BHS) cohort. The analysis was applied to all individuals (panel A), stratified by gender (panels B&C), and stratified by ethnic group (panels D&E), respectively.

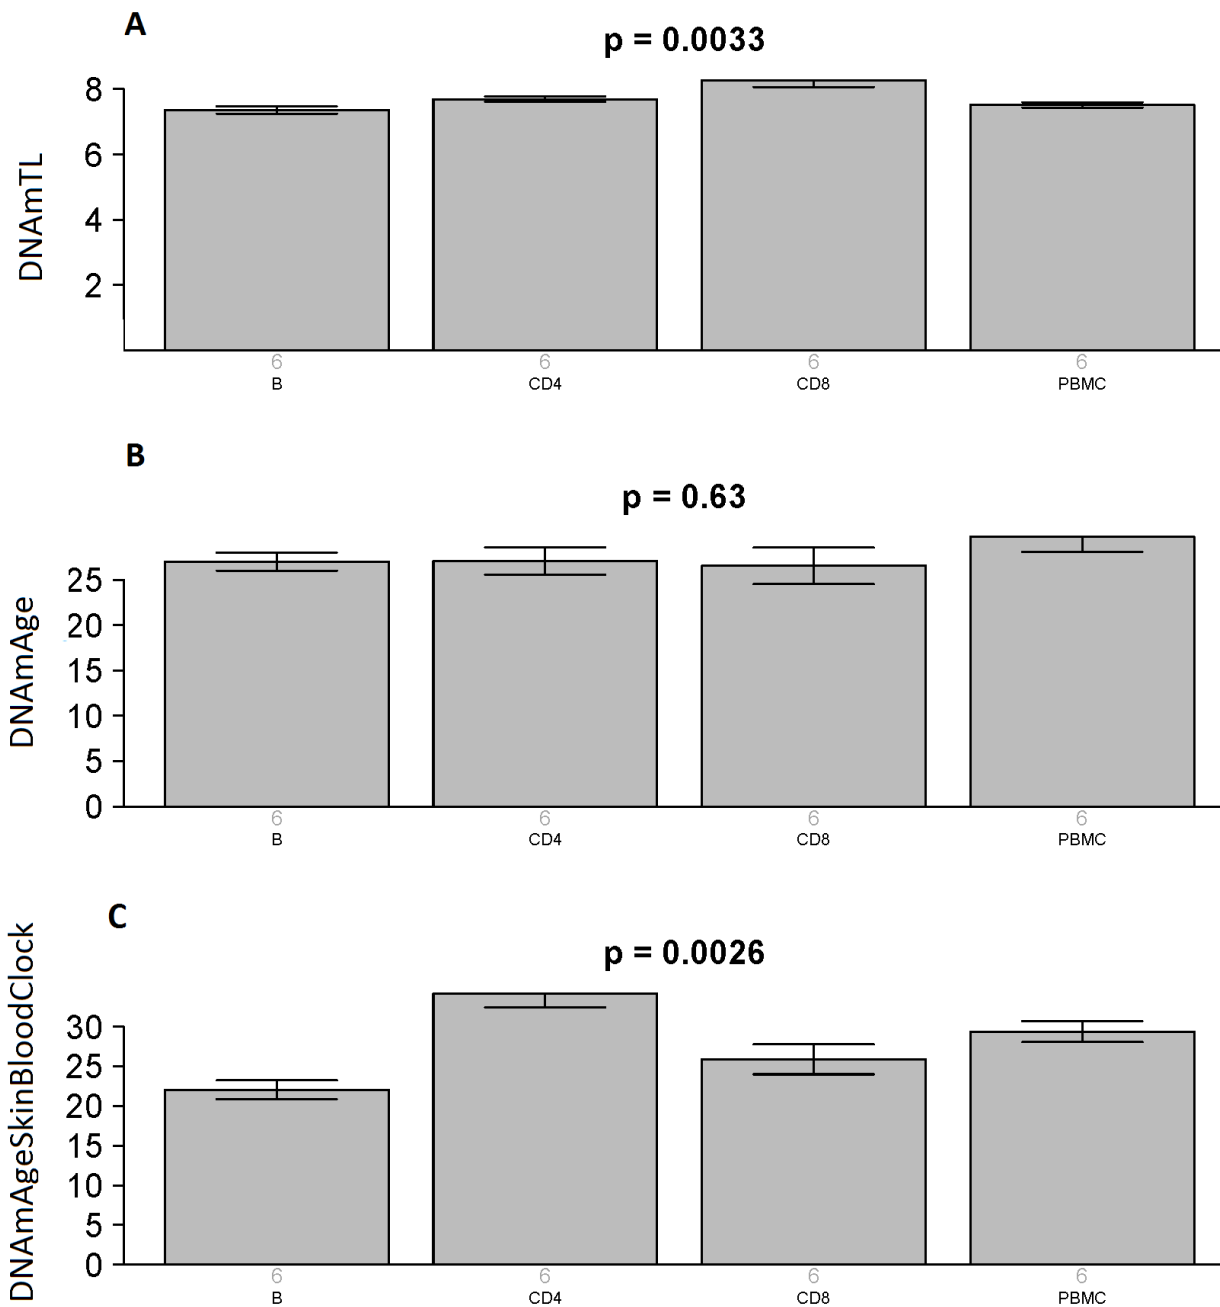

### Supplementary Figure 3. Application of DNAmTL in adipose tissues.

We applied DNAmTL to publicly available adipose methylation array data from n=648 female participants of the Twins UK study [23, 24]. (A) Scatter plot between DNAmTL (y-axis, in units of kilobase) and chronological age reveals a significant negative Pearson correlation coefficient ( $r = -0.42$ ). (B) Scatterplot between DNAmTL (y-axis) and TRF-based TL in n=21 individuals. (C) Age-adjusted DNAmTL (y-axis) versus body mass index. (D) Mean age-adjusted DNAmTL versus (current) smoking status (Kruskal Wallis test). DNAmTL did not differ between former smokers and never smokers, which is why we pooled these two categories. The data are available in ArrayExpress (data identifier EMTAB1866).

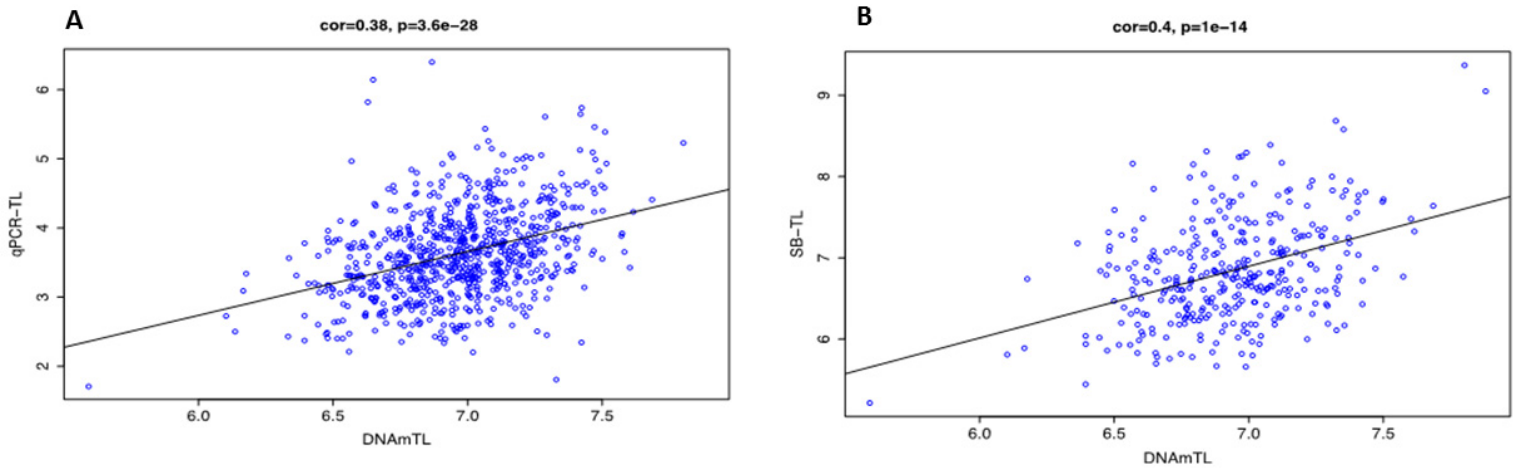

**Supplementary Figure 4. DNAm biomarkers across sorted blood cell types.**

We estimated DNAmTL (panel A), in contrast with DNAmAge [29] (panel B), and DNAmAgeSkinBlood [32] (panel C) across different blood cell types from 6 men aged from 27 and 32 years old. At each panel, we present Kruskal-Wallis P value for examining whether the distributions of the test DNAm biomarker are different across blood cell types.

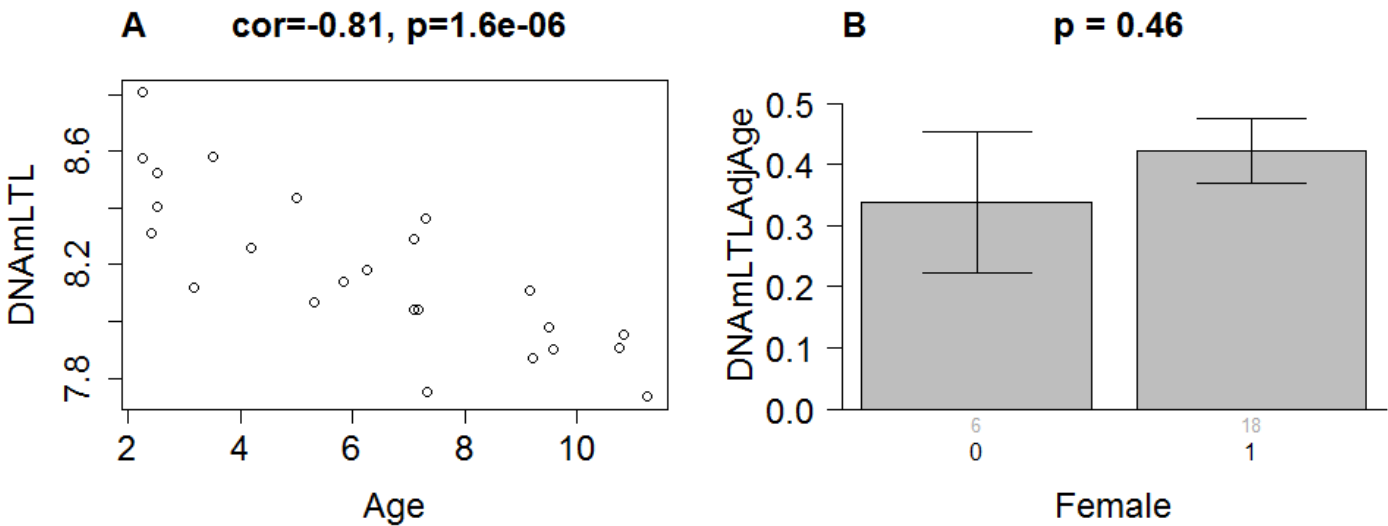

### Supplementary Figure 5. DNAm TL versus qPCR/southern plot TL in leukocytes.

We present the correlation analysis of DNAm TL (in units of kilobase [kb]) with panel (A) quantitative polymerase chain reaction (qPCR) based measured LTL (in units of kb) and with panel (B) southern plot based LTL, using 794 women from UK Twins study. Of the 794 women, 779 (98%) were available with qPCR TL and 346 (44%) were available with southern plot TL measures.

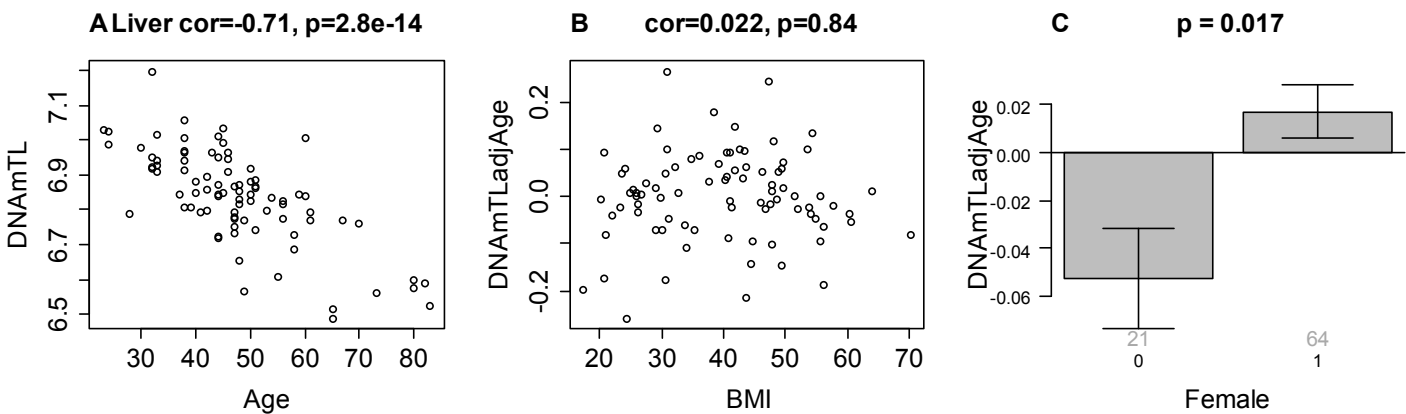

### Supplementary Figure 6. Application of DNAmTL in children.

We applied DNAmTL to publicly available array data from n=24 children who were younger than 13 years [25]. (A) Scatter plot of DNAmTL versus chronological age. (B) Age-adjusted DNAmTL versus gender.

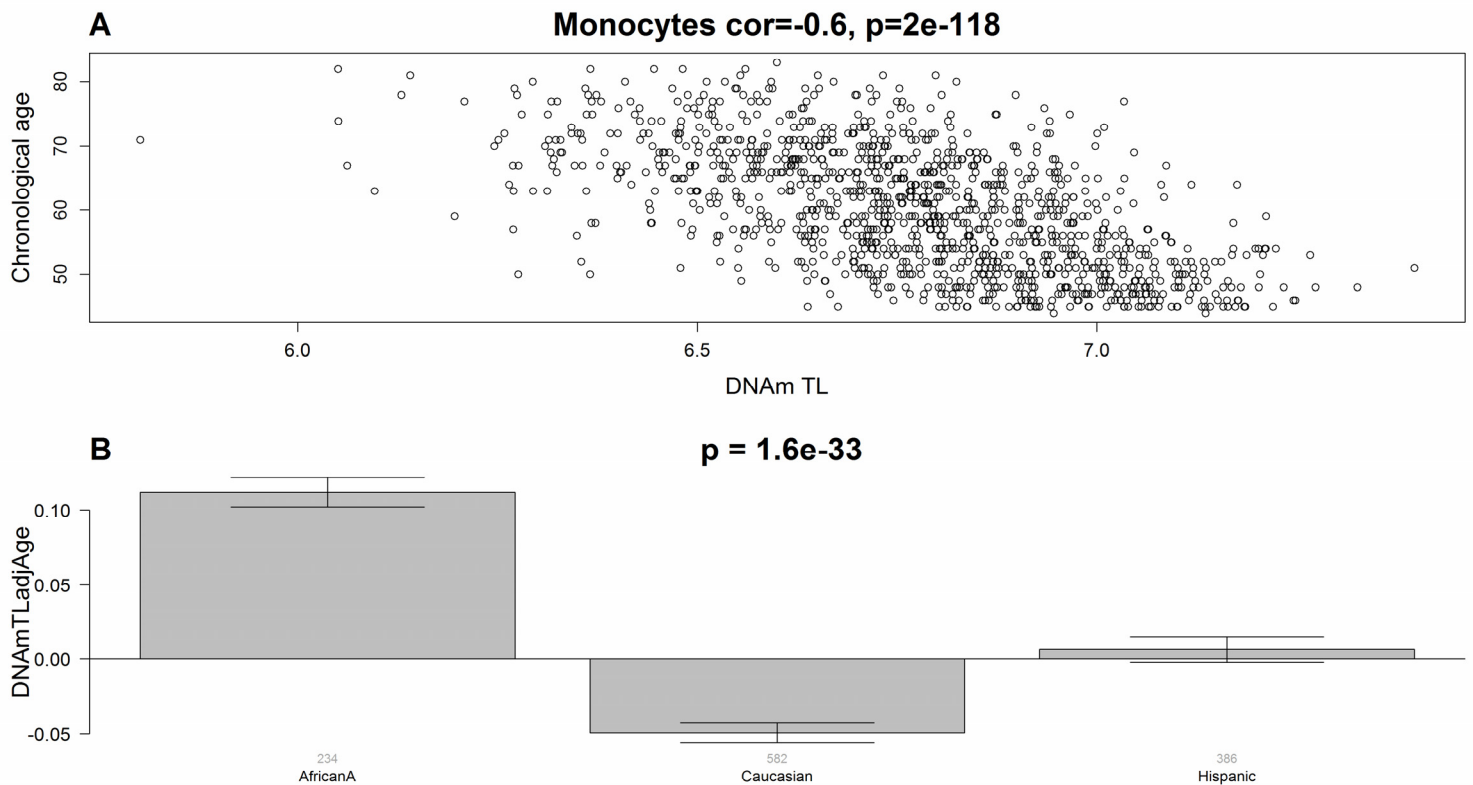

### Supplementary Figure 7. Application of DNAmTL on liver tissues.

We applied DNAmTL publicly available liver methylation array data from n=85 individuals (Gene Expression Omnibus GSE48325) [24, 33]. (A) Scatter plot between DNAmTL (y-axis) and chronological age and Pearson correlation test. (B) Scatter plot between DNAmTL and body mass index. (C) Mean Age-adjusted DNAmTL versus gender reveals that females have higher values of DNAmTLadjAge (Kruskal Wallis test).

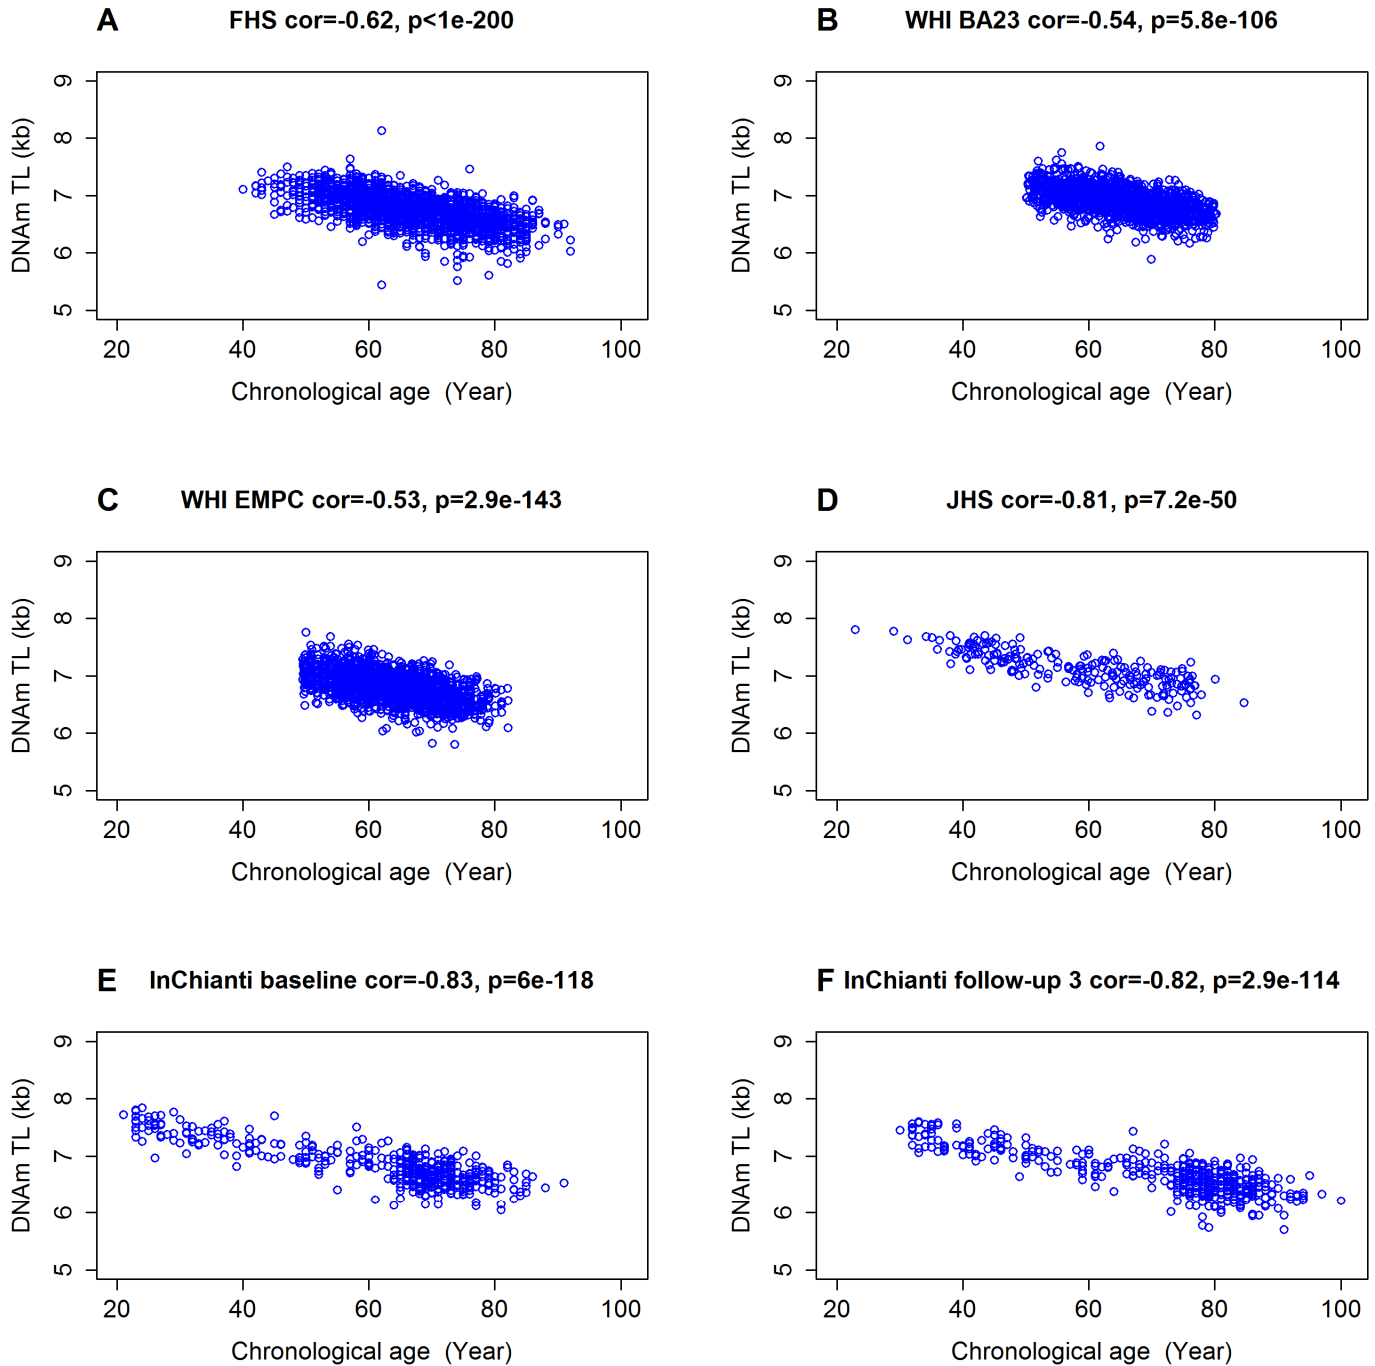

### Supplementary Figure 8. Application of DNAmTL on monocytes.

DNAmTL applied to publicly available DNA methylation data from n=1,202 purified monocytes samples from the Multi-Ethnic Study of Atherosclerosis (MESA) [34]. We checked (A) the correlation between DNAmTL and chronological age and (B) the association of age-adjusted DNAmTL with ethnicity. The data can be downloaded from Gene Expression Omnibus (GSE56047).

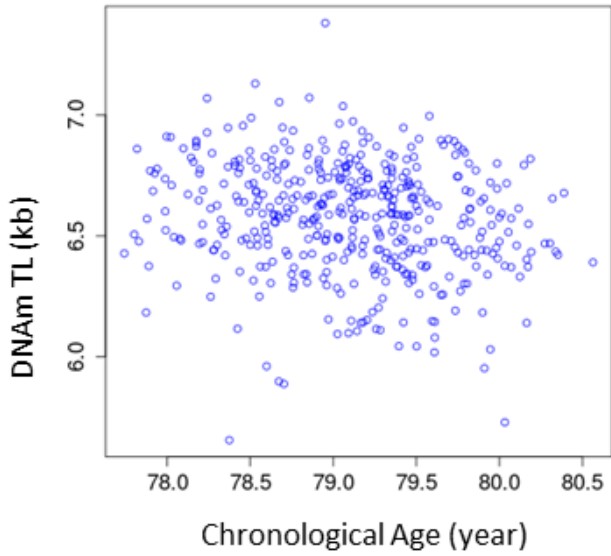

### Supplementary Figure 9. Correlation analysis of chronological age versus DNAmTL.

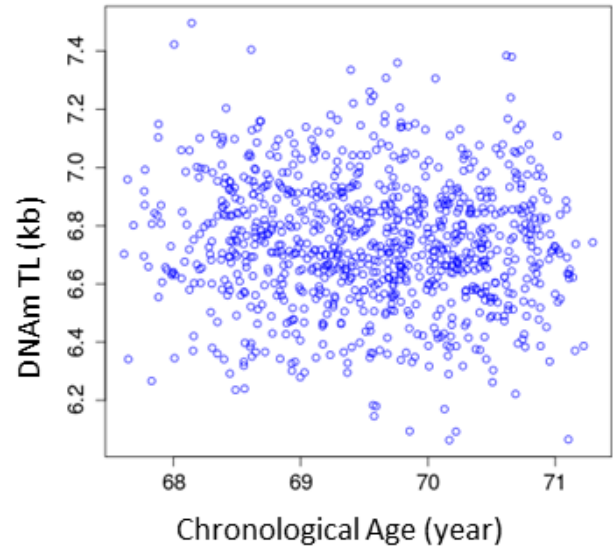

We present the scatter plots of DNA methylation based leukocyte telomere length (DNAmTL, in units of kilobase, y-axis) versus chronological age (x-axis, in units of year) for each validation dataset. The InChianti dataset was analyzed stratified based on baseline and follow-up visit. The weak correlation estimates in the Lothian *Birth* Cohort study (panels **G** & **H**) reflect that all subjects had similar ages (within 3 years). At each validation dataset, DNA methylation was profiled in blood tissues.

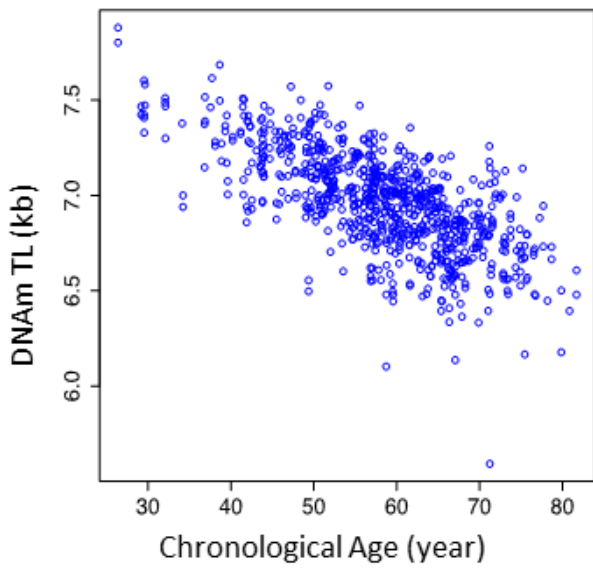

**G LBC1921**  $cor=-0.17, p=0.00036$

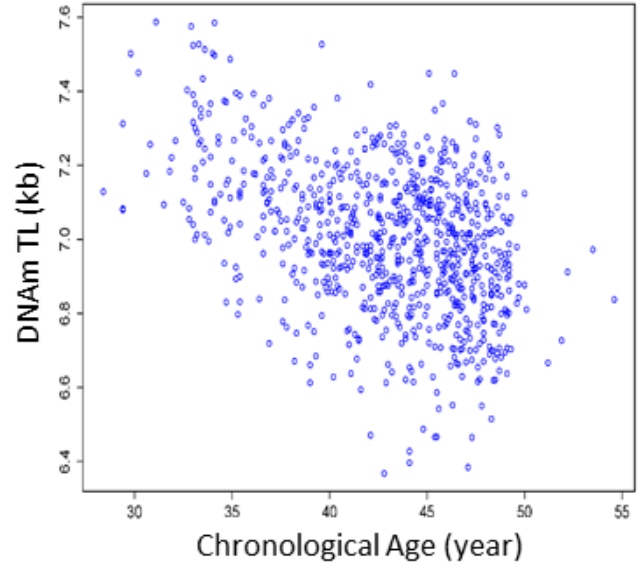

**H LBC1936**  $cor=-0.069, p=0.038$

**I UK TWINS**  $cor=-0.68, p=1.4e-108$

**J BHS**  $cor=-0.42, p=7.6e-37$

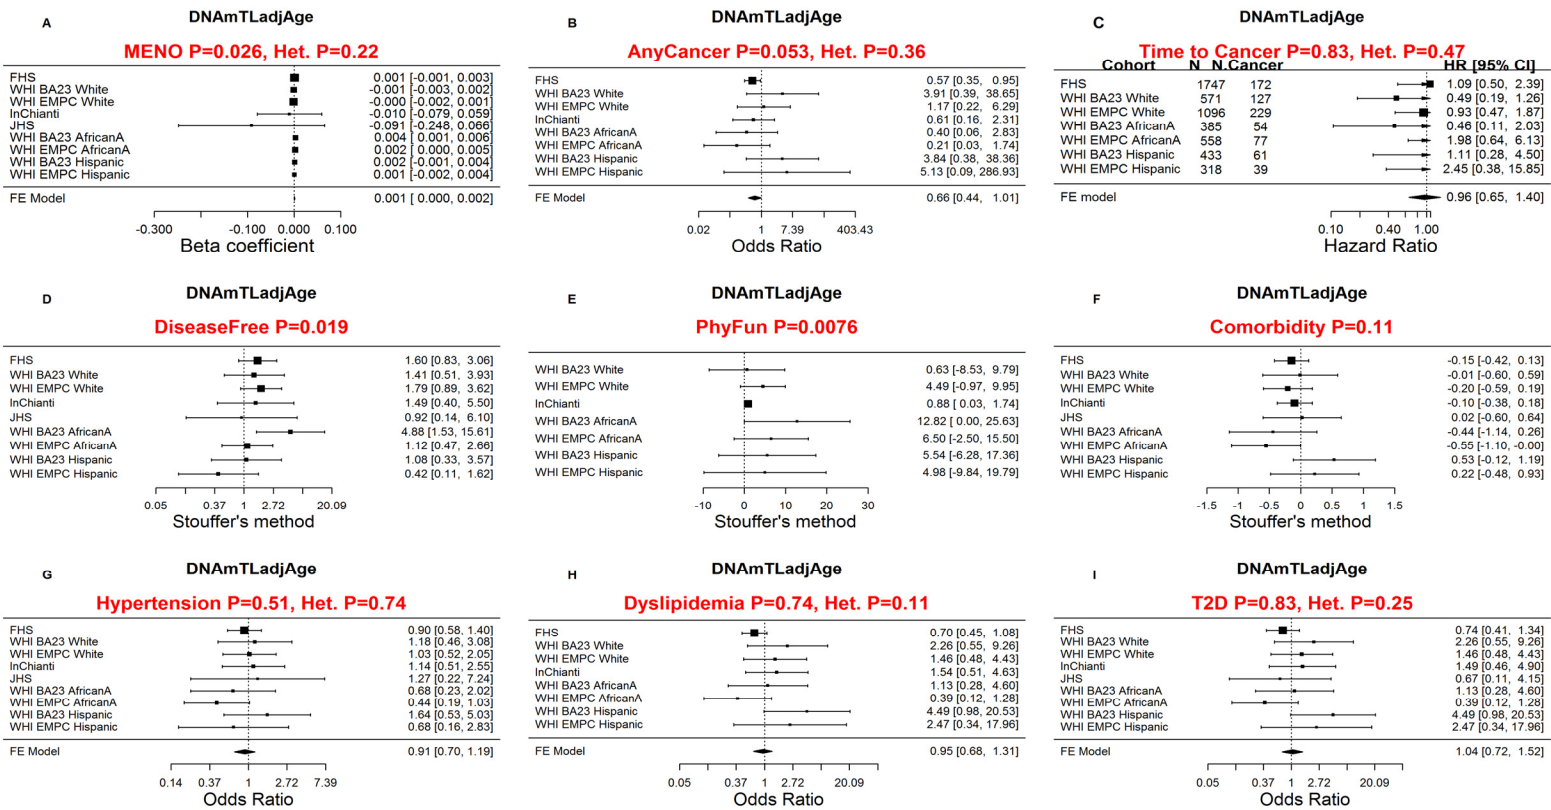

## Supplementary Figure 10. Meta analysis forest plots for associations with age-related conditions.

We present a meta analysis forest plot for combining the effect sizes of age-adjusted DNAmTL (DNAmTLadjAge) associated with age-related conditions: (A) age at menopause (effect size is beta slope corresponding to the age), (B) the odds ratio associated with any cancer, (C) the hazard associated with time-to-cancer, (D) the P value based on Stouffer's method that combined the P values of odds ratios associated with disease free, (E) the P value based on Stouffer's method that combined the P values of beta slopes associated with physical function, (F) the P value based on Stouffer's method that combined the P values of beta slopes associated with number of age-related conditions, (G) the odds ratio associated with hypertension, (H) the odds ratio associated with dyslipidemia, and (I) the odds ratio associated with type 2 diabetes. All but one (panel C) age-related conditions were aligned with the time of blood draw.

All the analyses were adjusted for gender and adjusted for intra pedigree correlation and batch effects as needed. Each panel report a meta analysis forest plot for combining the effect sizes (if based on fixed effect meta analysis) or the P values (if based on the Stouffer's method).

**Supplementary Figure 11. Marginal correlation analysis of lifestyle factors and biomarkers versus age-adjusted DNAmTL in the FHS.**

The rows of the table correspond to the associations of DNAmTLadjAge with diet, clinical biomarkers and measurements (e.g. Hemoglobin A1C), education and lifestyle factors. Using the FHS cohort, we analyzed females and males, respectively. The results were combined via fixed effect models weighted by inverse variance. We display the results from the meta analysis (All, in panel **A**), the analysis stratified by gender as listed in panel **B**. The columns report the available sample size (n) in the FHS cohort, the robust correlation coefficient (bicolor, based on the biweight midcorrelation coefficient [35]), and a p-value based on a linear effects model that also adjusts for the pedigree structure (implemented in the R package "nlme"). The bicor correlation coefficients is color coded (blue to red) across its range of [-1, 1]. P-values are color-coded in green (light to dark green scale).

**Supplementary Figure 12. Marginal correlation analysis of lifestyle factors and biomarkers versus age-adjusted DNAmTL in the WHI stratified by ethnicity.**

The rows of the table correspond to the associations of DNAmTLadjAge with diet, clinical biomarkers and measurements (e.g. C-reactive protein), education and lifestyle factors. Using the WHI cohort, we perform bicor correlation analysis for each ethnic group, respectively. The results were combined via fixed effect models weighted by inverse variance. We display the results from the meta analysis (All), and the analysis stratified by ethnic groups: White (N up to 1635), African American (N up to 924), and Hispanic (N up to 719). The columns report the available sample size (N) in the WHI cohort, the robust correlation coefficient and P value (bicor, based on the biweight midcorrelation coefficient [35]). The bicor correlation coefficients is color coded (blue to red) across its range of [-1, 1]. P-values are color-coded in green (light to dark green scale).

| Category           | Variable                 | ALL       |       |         | White   |       |         | AfricanA |       |         | Hispanic |       |         |

### Supplementary Figure 13. Age-adjusted DNAm TL significantly associated with smoking status.

We present association analysis of age-adjusted DNAm TL with smoking status (current versus never/former smokers), using Bogalusa Heart Study (BHS, N=831) cohort. Our analysis showed that current smokers were associated with significant shorter age-adjusted DNAm TL in the whole samples (panel A) and in each subgroup stratified by gender (panels B & C) or ethnicity (panels D & E).

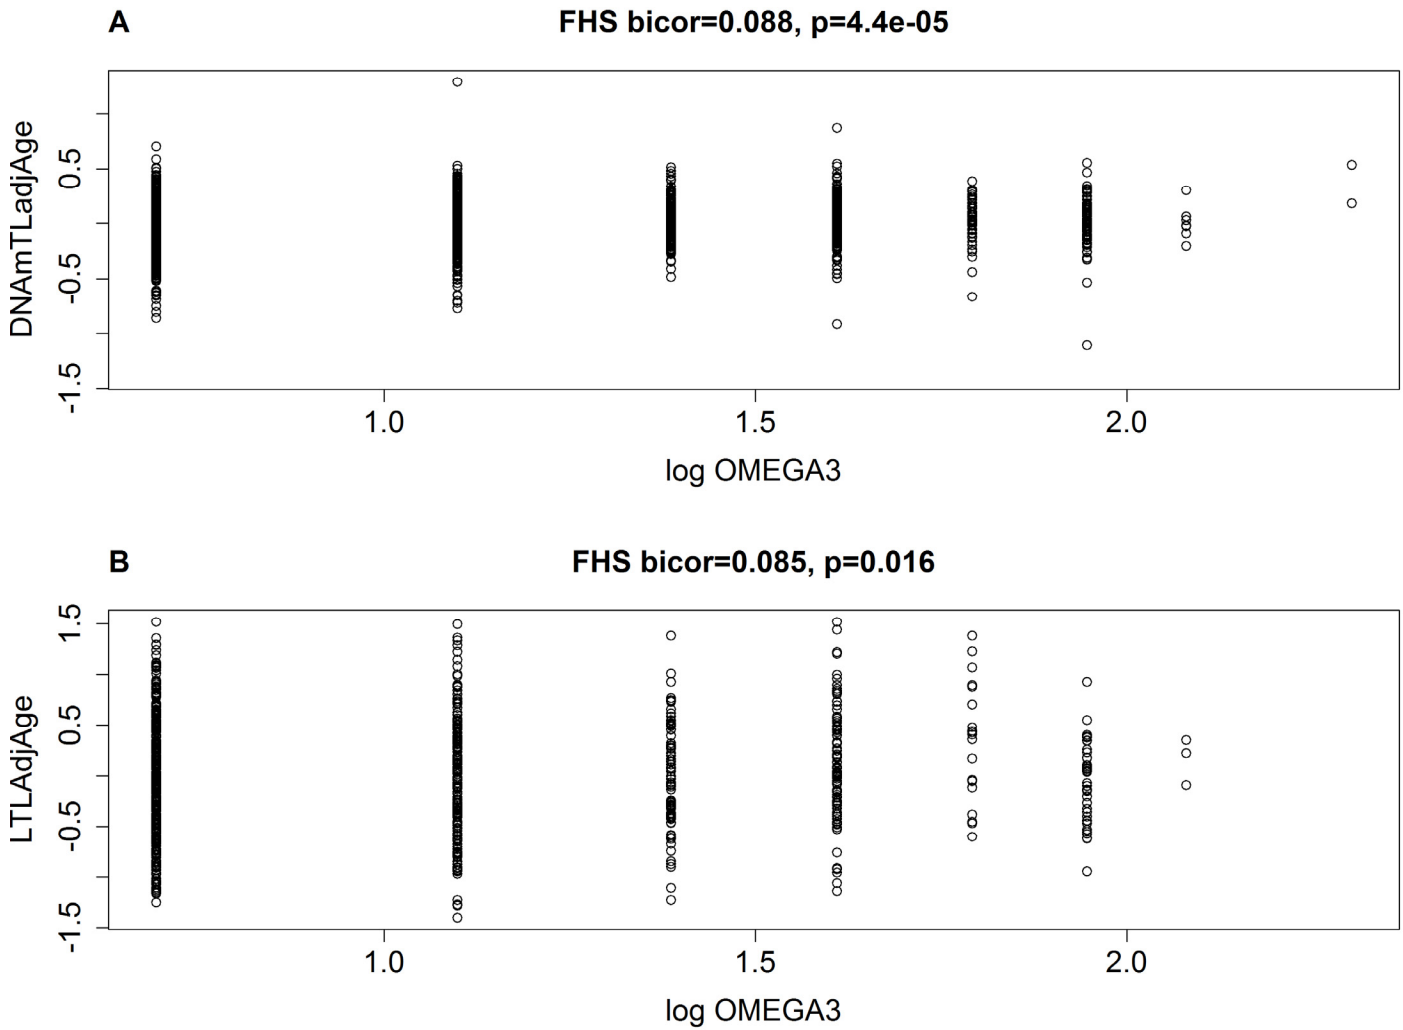

### Supplementary Figure 14. Age-adjusted LTL not affected smoking status.

We present association analysis of age-adjusted LTL with smoking status (current versus never/former smokers), using Bogalusa Heart Study (BHS, N=831) cohort. Our analysis showed that current smokers were not associated with significant shorter age-adjusted DNAm TL in the whole samples (panel A) and in each subgroup stratified by gender (panels B & C) or ethnicity (panels D & E).

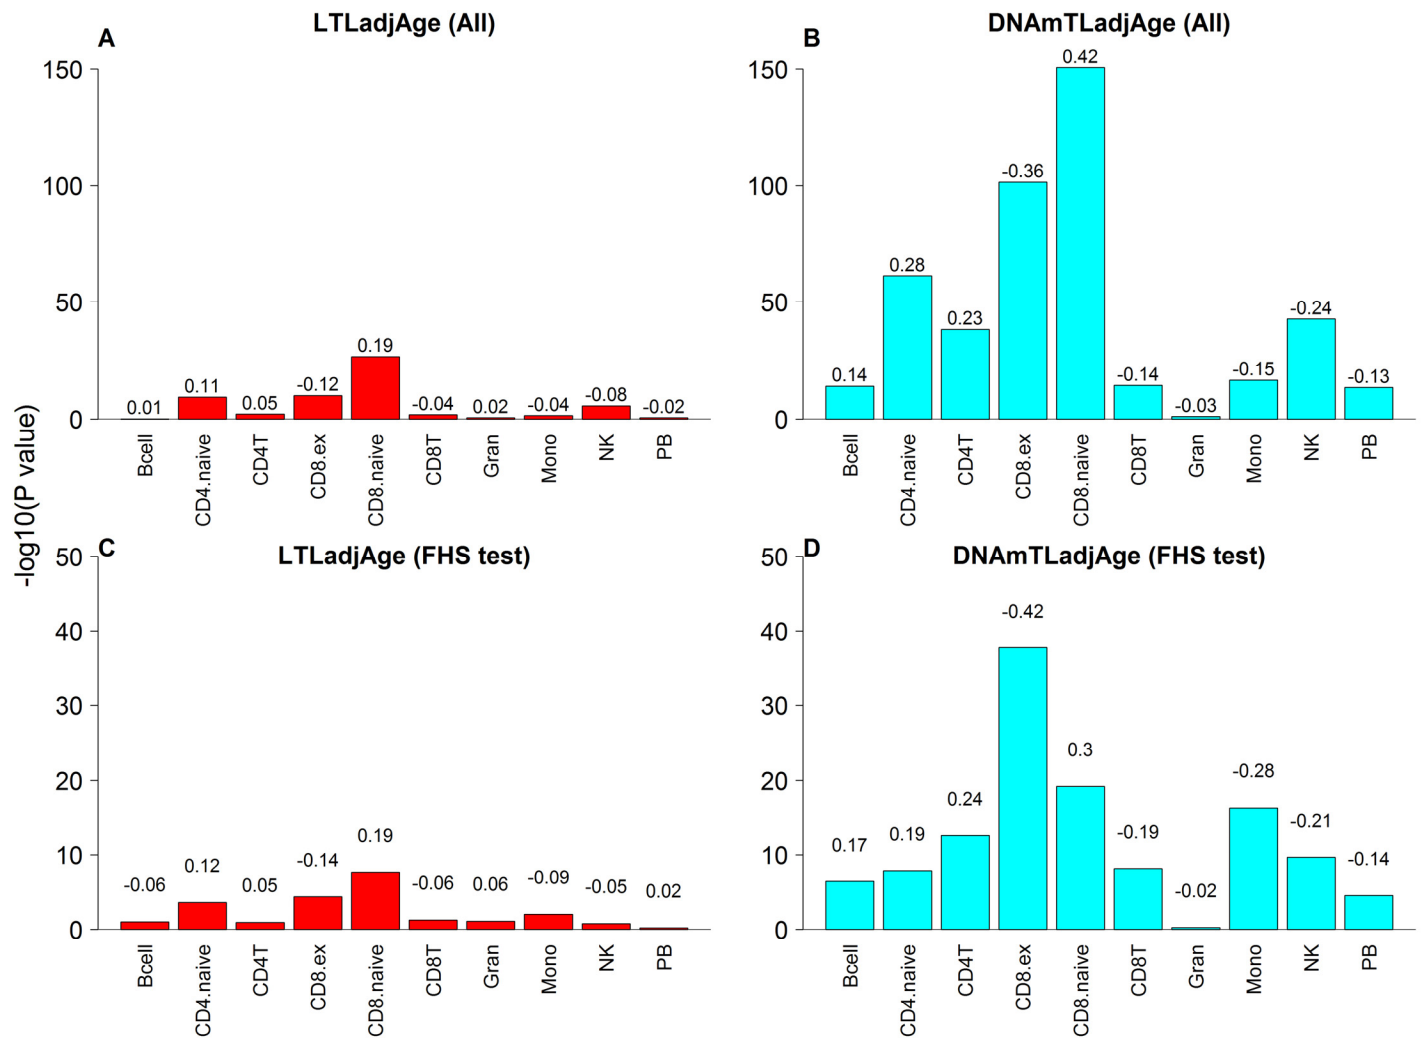

**Supplementary Figure 15. Impact of OMEGA3 on age-adjusted leukocyte telomere length measures.**

We investigated the impact of OMEGA-3 FATTY-ACIDS supplement on age-adjusted DNAmTL (DNAmTLadjAge) and age-adjusted LTL (LTLadjAge), respectively. The variable of OMEGA-3 intake was log transformed,  $\log(\text{OMEGA-3}+1)$ , to improve its normality. Panel **A** presents the robust correlation analysis using the entire FHS cohort (N=2147) and Panel **B** presents the robust correlation analysis based on the 878 individuals whom were available with LTL measures based on terminal restriction fragmentation (TRF) method.

### Supplementary Figure 16. Measures of blood cell composition versus leucocyte telomere length measures.

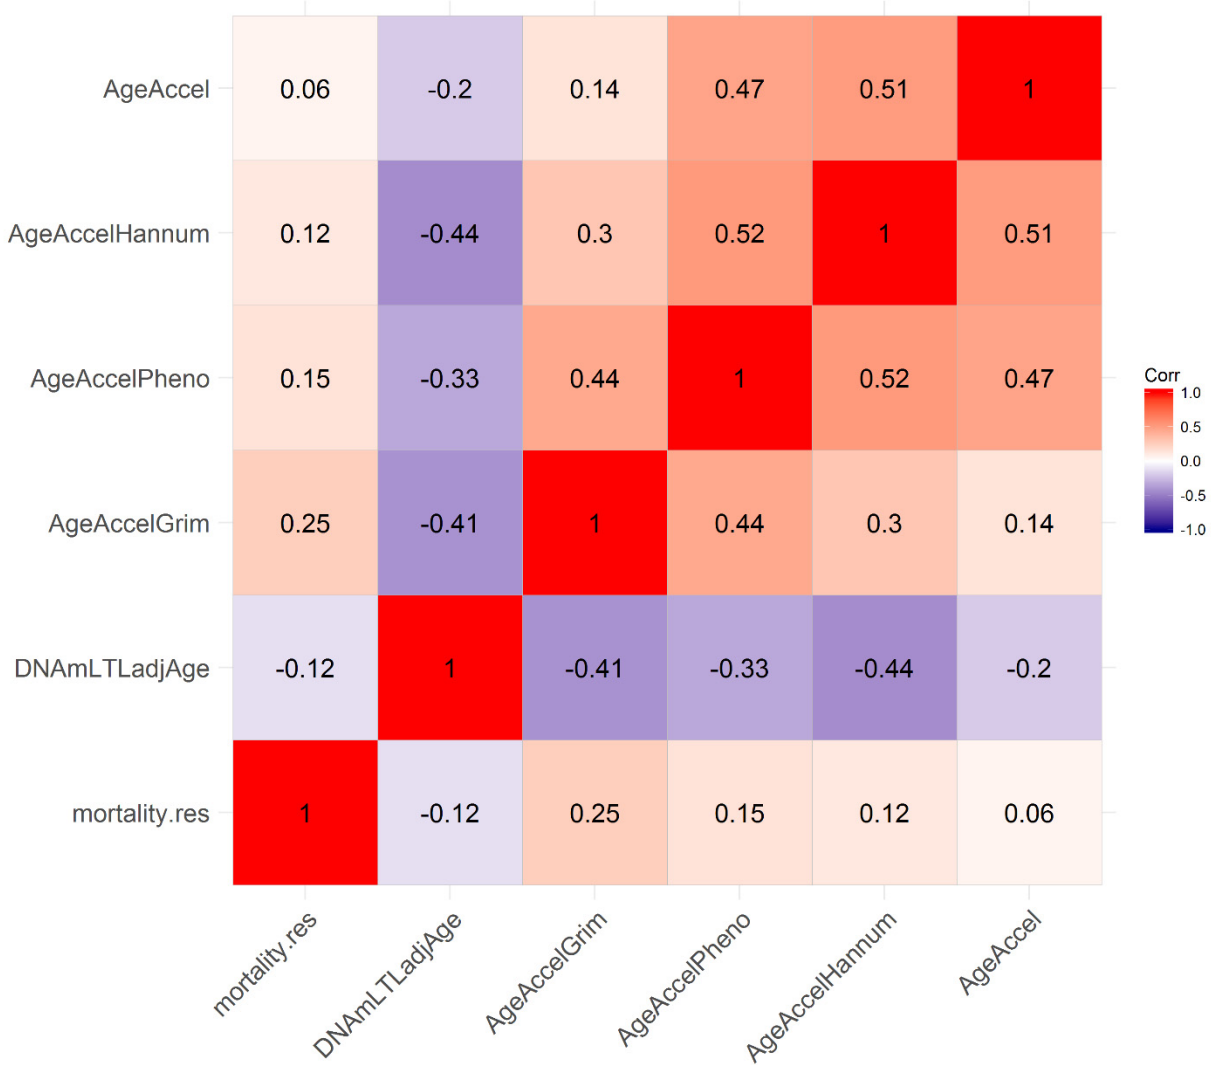

We present the bar plots to depict the associations of age-adjusted leucocyte telomere length (LTL) and its surrogate age-adjusted DNAmTL with 10 imputed measures of blood cell counts, respectively. The height of each bar corresponding to the statistical significance level (meta analysis p-value) of an association test between the blood cell measure and the age-adjusted biomarker. More precisely, the y-axis presents minus logarithm (base 10) transformed meta P values. The numbers displayed on top of each bar are the meta analysis estimates of the correlation coefficients. The association analysis is *not* confounded by chronological age because we used age adjusted biomarkers. Panels **A** and **B** present the fixed effects meta analysis (N=3,134) performed across two training dataset: WHI BA23 (N=718) and JHS (N=1538), and one test dataset: FHS (N=878). Sensitivity analysis was performed on the test dataset only (FHS) to demonstrate the results not biased by the training process. Abbreviations for cell counts are listed in the following: nature killer (NK), monocyte (MONO) and granulocyte (Gran), CD8pCD28nCD45Ran (CD8.ex for exhausted cytotoxic T cells), and plasma blast (PB). The blood cell counts were imputed based on DNA methylation levels as described in [28, 36] and the **Supplementary Methods section** (above).

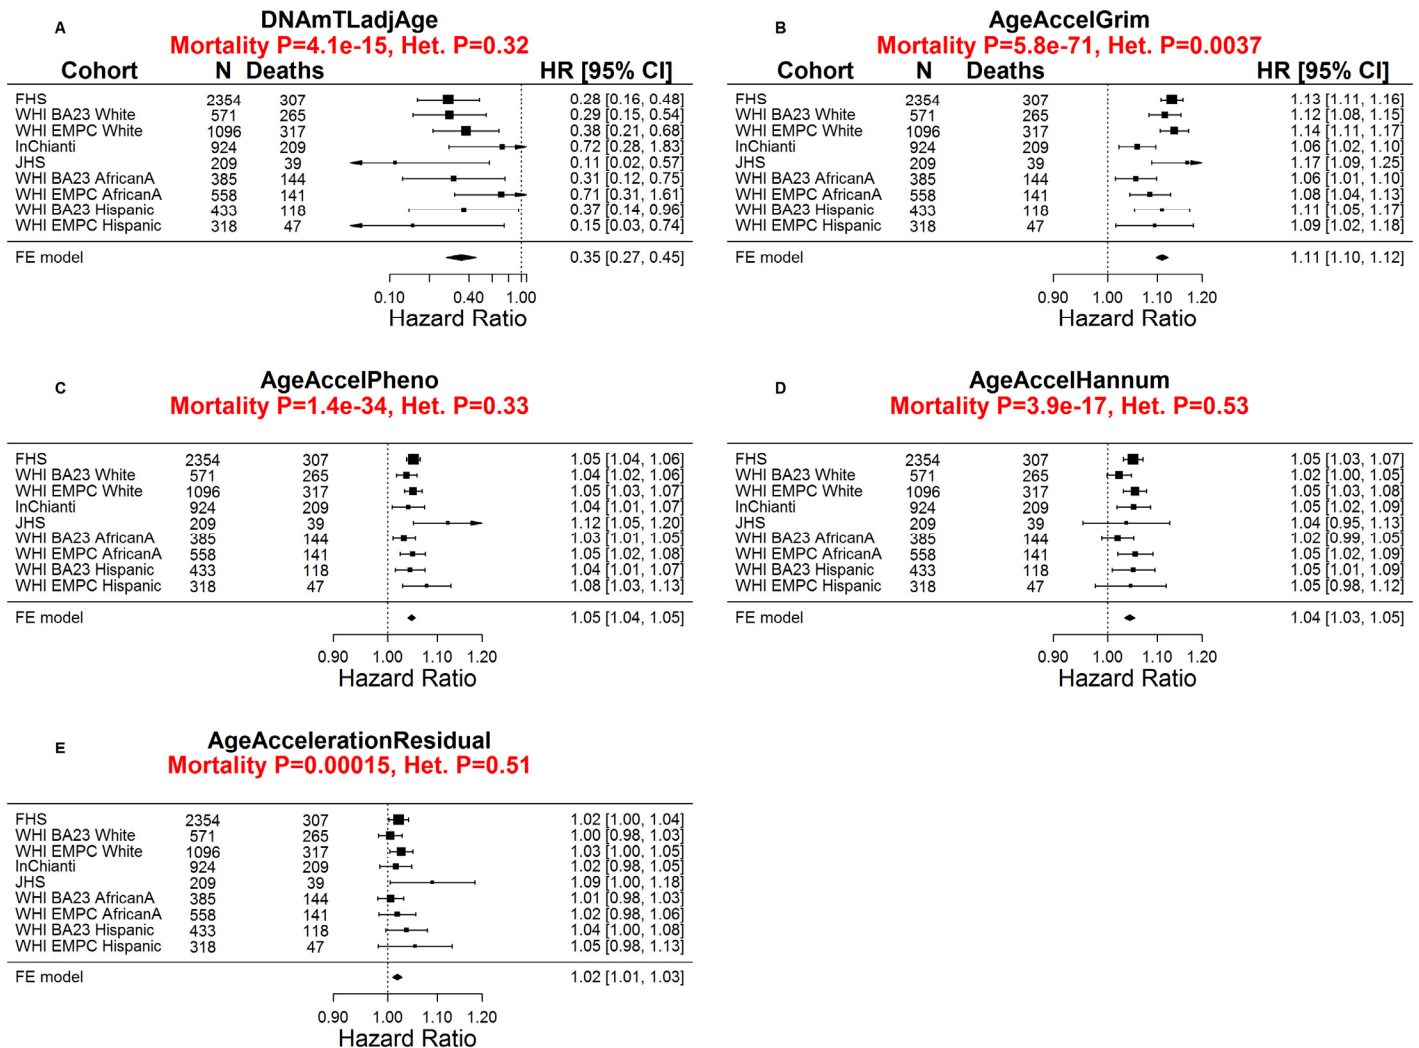

**Supplementary Figure 17. Heat map of pairwise correlations of DNAm based biomarkers.**

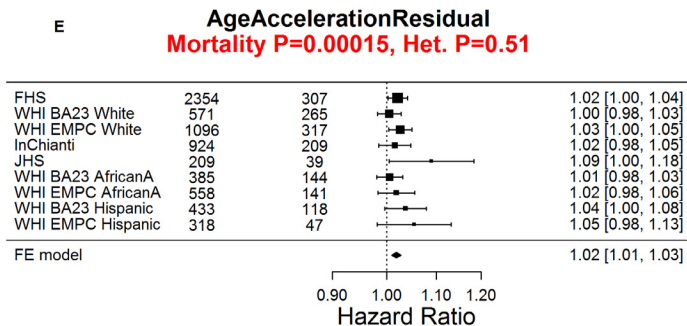

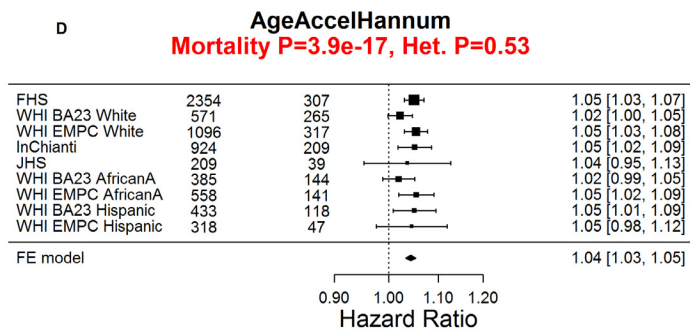

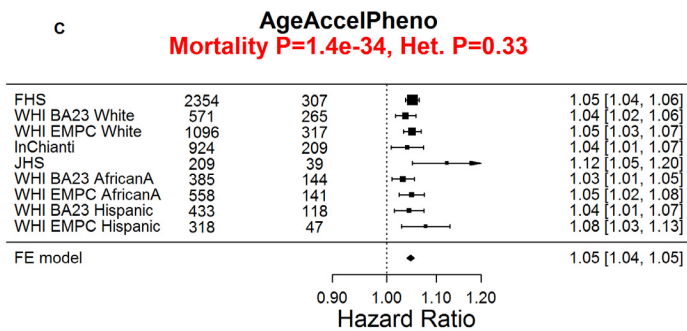

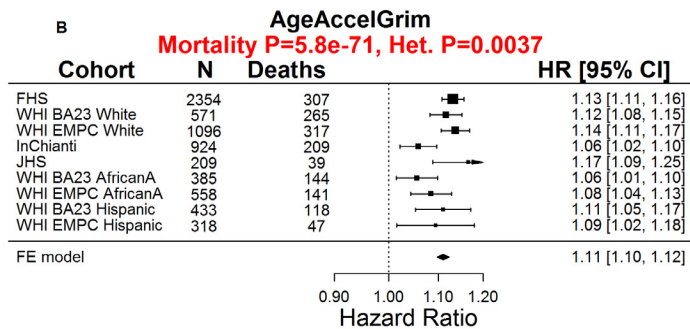

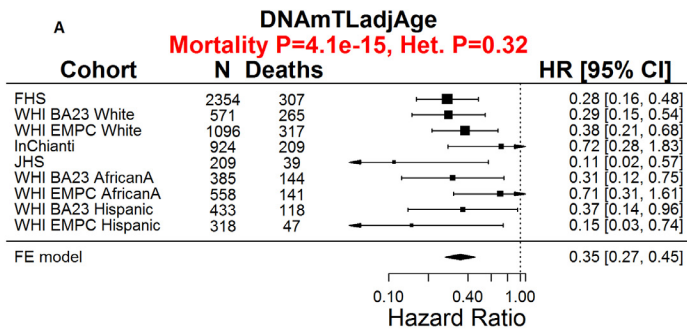

The heat map color-codes the pairwise Pearson correlations of DNAmTLadjAge and four epigenetic age acceleration measures: AgeAccelGrim [37], age-adjusted DNAm PhenoAge (AgeAccelPheno) [38], age-adjusted DNAm age based on Hannum et al. (AgeAccelHannum) [39], and age adjusted DNAm age based on Horvath (AgeAccel) [29], performed using the Framingham Heart Study (N=2356). The figure also includes an estimator of mortality risk, mortality.res, which can be interpreted as a measure of "excess" mortality risk compared to the baseline risk in the test data. Formally, mortality.res is defined as the deviance residual from a Cox regression model for time-to-death due to all-cause mortality. The shades of color (blue, white, and red) visualize correlation values from -1 to 1. Each square reports the Pearson correlation coefficient.

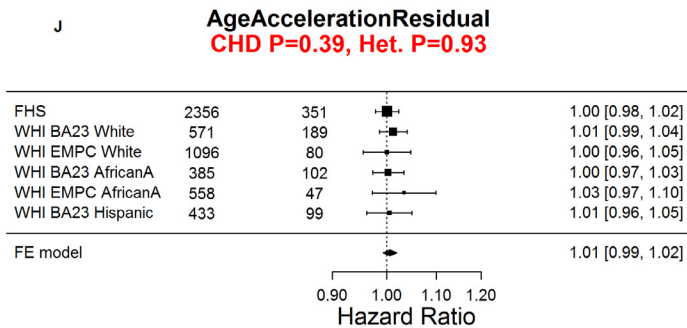

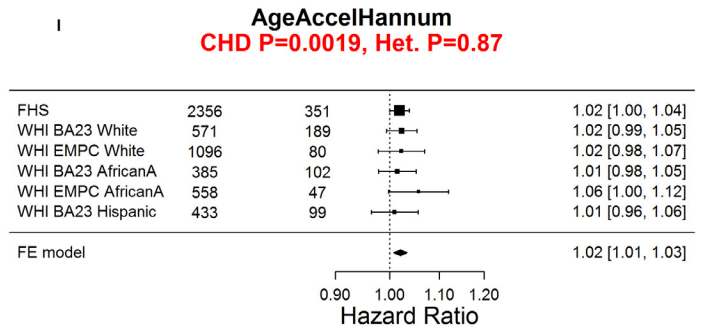

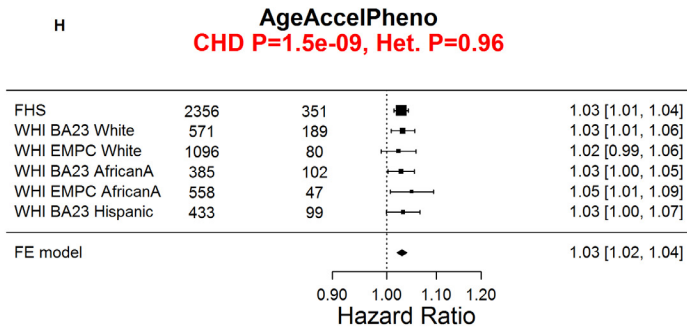

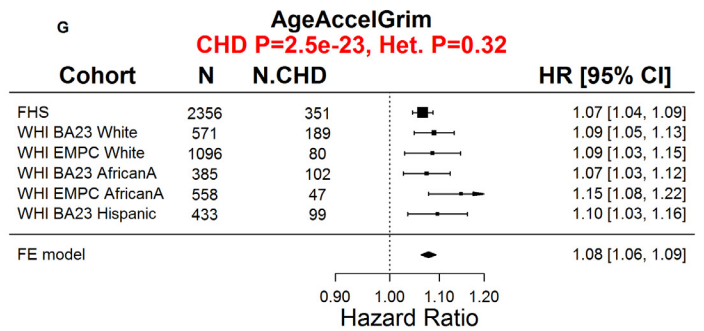

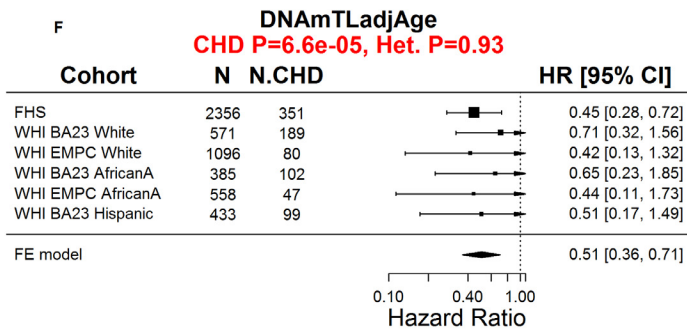

**Supplementary Figure 18. Comparing DNAmTLadjAge and epigenetic measures of age acceleration in predicting life and health span.**

We compare age-adjusted DNAmTL (DNAmTLadjAge) with four well-known epigenetic measures of age acceleration: 1) age-adjusted DNAm GrimAge based on Lu et al. [37], (AgeAccelGrim), 2) age-adjusted DNAm PhenoAge (AgeAccelPheno) [38], 3) age-adjusted DNAm age based on Hannum et al. (AgeAccelHannum) [39], and 4) age adjusted DNAm age based on Horvath (AgeAccelerationResidual) [29], for their associations with life and health span. Three survival outcomes, time-to-death (panels A-E), time-to-coronary heart disease (CHD, panels F-J), and time-to congestive heart failure (CHF, panels K-O), were evaluated across each available validation dataset, stratified by race/ethnicity. Cox regression analysis was performed to predict the hazards of DNAmTLadjAge and each epigenetic measures of age acceleration variables, adjusted for age, gender and adjusted for intra pedigree correlation and batch effects as needed. Each row presents the summary statistic at a (stratified) study dataset and reports sample size (N), number of events, P value, hazard ratio and a 95% confidence interval resulting from a Cox regression model. Panels (A-O) are based on all the available validation datasets. As parts of the FHS cohort were used to train the DNAm GrimAge, we performed sensitive analysis that removed the entire FHS cohort and observed similar patterns (Panels).

# Sensitivity analysis

**Supplementary Table 1: Direct comparison of DNAmTLadjAge with LTLadjAge for predicting time-to-death in WHI and JHS test data.**

We compare age-adjusted DNAmTL (DNAmTLadjAge) with age-adjusted TRF-based leukocyte telomere length (LTLadjAge) for their associations with mortality, using the WHI BA23 test (N=100) and JHS test (N=100) data. The analysis using the WHI BA23 data was stratified by race/ethnicity. Cox regression analysis was performed to predict the hazards of age-adjusted telomere length variables, adjusted for age and gender. Hazard ratios (HR) correspond to one kilobase longer of age-adjusted telomere length.

| Test Data | Race     | Variable     | Sample Size | Number of deaths | HR    | P value         |

## Supplementary Table 2: Overview of the cohorts used in the validation analysis

The table summarizes the characteristics of 9,345 individuals from a total of nine independent cohorts across seven studies that were used in our validation analysis. For example, up to two longitudinal measurements were available for each of the 484 individuals from the InChianti cohort.

| Cohort      | N            | Age                        | Smoking status |        |         | Years of Follow-up         |

Age is presented in the format of mean ± SD [range]

Years of follow-up are presented in the format of mean ±SD [25<sup>th</sup>, 75<sup>th</sup>].

\*The distribution of age is based on exam 8.

\*\*The statistics are based on the number of 924 observations across 484 individuals.

### Supplementary Table 3: Stratification analysis of time-to-death predicted by age-adjusted

#### DNAmTL

Meta analysis for combining hazard ratios (HR) predicting time-to-death based on age-adjusted DNAmTL (DNAmTLadjAge), stratified by different subgroup. At each subgroup of each study set, the analysis was further stratified by racial group that we limited the analysis with number of events  $\geq 20$ . We list the following columns: group for stratification, stratified level, sample size, number of events, number of data combined in the meta analysis, HR and P values. The categories associated with BMI ranges are a) normal 18.5 -25 (normal), b) 25 to 30 (over), and c) >30 (obese). The categories I to IV associated with education attainment (EDU) are I) less than high school, II) high school degree, III) some college, and IV) college degree and above. The other abbreviations are HYPT (hypertension) and T2D (Type 2 diabetes). Each HR corresponds to one kilobase longer of age-adjusted DNAmTL. The P values < 0.05 are marked in bold.

| Strata        | Level           | N    | Death | Number of data | HR   | P              |

### Supplementary Table 6. Hypergeometric tests of the 140 DNAm TL CpGs enriched with telomere regions

The table below presents enrichment analysis for evaluating the overlap between the 140 CpGs comprising our DNAm TL model and the CpGs nearby telomere regions from 3 mega base (Mb) at each chromosome tail. We list the following columns: region threshold, the number of CpGs located nearby telomeres ( $N_{\text{CpG-TL}}$ ), the proportion of  $N_{\text{CpG-TL}}$  divided by total number of whole genome CpGs ( $N=4,53,093$ ) present in both 450k and Epic array, and hypergeometric P values. We also performed sensitivity analysis based on a variety of regions thresholded at 2, 4, 6 and 8 Mb respectively.

| Region (Mb) | $N_{\text{CpG-TL}}$ | Proportion  | $N_{\text{overlap}}$ | Hypergeometric P |
|-------------|---------------------|-------------|----------------------|------------------|
| 2           | 50230               | 0.11        | 26                   | 5.9E-03          |
| <b>3</b>    | <b>67523</b>        | <b>0.15</b> | <b>32</b>            | <b>8.1E-03</b>   |
| 4           | 81835               | 0.18        | 34                   | 3.9E-02          |
| 6           | 101312              | 0.22        | 44                   | 8.3E-03          |
| 8           | 117269              | 0.26        | 48                   | 1.7E-02          |
| 10          | 132541              | 0.29        | 52                   | 2.7E-02          |

## Supplementary Table 7: GWAS of DNAmTLadjAge on Leukocyte telomeres associated loci

The table relates genome-wide significant associated SNPs of leukocyte telomere length (LTL) to age-adjusted DNAmTL (DNAmTLadjAge). We presented 14 SNPs associations across 10 distinct susceptibility loci associated with LTL from three large-scale studies: (I) meta-analysis association of LTL in chromosome 5 *TERT* only (N=53,724)<sup>40</sup>, (II) a genome-wide meta-analysis of LTL (N=37,684)<sup>41</sup>, and (III) a genome-wide meta-analysis of LTL (N=26,089)<sup>42</sup>. Each row presents a genome-wide significant locus associated with LTL in a given study, except chromosome 16 *MPHOSPH6* and chromosome 20 *BCL2L1* just slightly below genome-wide significance and highlighted by the corresponding studies as major findings. The listed markers are the leading SNPs with the most significant P values associated with LTL at a given study and locus, sorted by chromosome and position. The table presents SNP associations for DNAmTLadjAge and age-adjusted LTL (LTLadjAge) respectively, using FHS cohort (N=811). The association analysis was based on linear mixed analysis with the random covariance matrix determined by Kinship coefficients for pedigree structure, adjusted for gender and three principle components as fixed effects.

| Study | SNP        | bp        | Gene     | A1 | DNAmTLadjAge |          | LTLadjAge |                 |
|-------|------------|-----------|----------|----|--------------|----------|-----------|-----------------|
|       |            |           |          |    | $\beta$      | P        | $\beta$   | P               |
